Omnican® fine

HOW TO USE

Remove peel paper.

Place needle onto injection device. Keep straight.

Screw needle onto injection device. Ensure a tight fit.

Remove needle container and set aside for removing pen needle from pen later.

Pull needle shield off without tilting it.

Check functionality according to instructions for use of injection device.

Dial and inject according to instructions for use of injection device. After the injection, leave the needle in the fatty tissue for about 10 seconds. This prevents leakage.

Carefully put needle container back on needle. Unscrew it with container from pen and discard.

Recommended method of disposal: Use of medical sharps collector such as the Omnican® box or Medibox®.

4 mm 32G 6 mm 32G Ultra-thin-wall technology

4 mm 31G 6 mm 31G 8 mm 31G Extra-thin-wall technology
Choose a needle length and a suitable injection technique. Pinch up for needles longer than 6 millimeter.

Use a new pen needle for every injection.

Perform an air shot before every injection to ensure that the insulin flow is steady.

If you pinch up, use your thumb, index and possibly your middle finger. Gently pinch the fatty tissue underneath the skin away from the muscle and create a skin fold.

Always inject directly into the skin. And remember to always inject into healthy fatty tissue.

After the injection, leave the needle in the fatty tissue for at least 10 seconds. This prevents leakage.

Change injection spots to prevent lipohypertrophies (short: lipos).

After injection, dispose of the needle straight away according to local regulations. Use the outer needle container to do so.

Avoid intramuscular injection. It is not only painful, but the insulin will be absorbed irregularly.

Don’t use a needle more than once, because it is no longer sterile, the tip gets damaged – injecting hurts more and may cause lipos. Residues may block the needle.

Never inject insulin without having checked that the needle is blockage free.

Don’t squeeze too hard, since you will pinch up the muscle as well. This will increase the risk of intramuscular injections.

Never inject through your clothes. The silicone finish rubs off, the delicate tip gets bent, and shreds of fabric might block the needle or even enter your skin.

Don’t pull the needle out directly after injection.

Never inject into the same spot more than once in a row; the risk of lipos forming is too high.

Don’t recap the needle to reuse it. This is no protection and it is no longer sterile. And you might hurt yourself, since the needle shield is small.
